Exception Handling

1st → try: → first tries to execute this block.

2nd if error → except: → if any error, then this block

3rd if no error → else: → if no error, then this after try:

4th always → finally: → This will always execute at the end.

```
try:
    except Error name as ex:
        print(ex)
```

→ will print exact error
→ has to be exact.

```
try:
    except :E1 as e:
    except Exception as e1:
        print(e1)
```

→ main parent class of Exceptions
→ always use after other exceptions.
→ gives exact error.

Error types
- → NameError
- → ValueError
- → ZeroDivisionError
- → etc

eg → in file handling

```
try :
    file = open ('eg.txt','r')
    content = file.read()
    print (content)

except Exception as e:
    print (e)

else :
    print ('File accessed')

finally :
    if 'file' in locals() and not file.closed():
        file.close()
        print ('File closed')
```

- Try → tries to read a file.
- except → prints the error if any.
- else → if no error, prints file accessed.
- finally → if file was opened & not closed, closes the file.
